

Kestrel Voice Agent – API Tool Testing Report

30 September 2026

1. Overview

This report documents API tool testing for the Kestrel Voice Agent project. The captured Swagger interface was used to send requests to the local /api/tools endpoint and inspect the returned JSON responses. The screenshots show tests of the check_eligibility tool and the search_knowledge_base tool.

2. Testing environment and request flow

The requests shown in the screenshots target `http://127.0.0.1:8000/api/tools` and use an `application/json` request body. The displayed responses use HTTP status code 200. The examples include a `toolCallList` entry with a tool ID, function name, and arguments; the server returns a `results` array containing the matching `toolCallId` and a result.

Note: the screenshots demonstrate local endpoint tests. They do not, by themselves, prove that a Vapi assistant was created or that a live phone call was completed.

3. Test cases and observed results

Test 1 – Eligibility check: borderline credit score

Input shown: entity type = proprietorship; vintage = 3 years; annual turnover = ₹40 lakh; requested loan amount = ₹10 lakh; owner age = 35; GST registered = true; credit score = 680.

Observed result: status = borderline. The response cites a credit score between 650 and 700 as a reason for manual review. It states that the case is preliminary only and should be submitted for document verification and credit approval; it does not guarantee approval.

Test 2 – Eligibility check: not eligible

Input shown: entity type = proprietorship; vintage = 3 years; annual turnover = ₹15 lakh; requested loan amount = ₹10 lakh; owner age = 35; GST registered = true; credit score = 720.

Observed result: status = not_eligible. The response lists annual turnover below ₹20 lakh and a requested amount above 50% of annual turnover (the stated working-capital limit) as reasons.

Test 3 – Knowledge-base search: home-loan query

Input shown: query = “do you offer home loans”. The response is NO_RELEVANT_INFORMATION and says the knowledge base has nothing reliable on this. It instructs the agent to tell the customer it does not have that information and offer a callback or human colleague, rather than guessing.

4. Summary

The captured tests show that the API returned structured results for three tool calls: a borderline eligibility outcome, a not-eligible outcome, and a no-relevant-information response from the knowledge-base search. The first two responses include reasons, while the knowledge-base response provides a safe fallback for unsupported information.

5. Conclusion

The screenshots provide evidence that the local API endpoint responded successfully to the shown requests and returned the expected style of tool results. The eligibility outputs should be treated as preliminary responses only, as the API message itself states that final approval requires document verification and credit approval. Further end-to-end testing with a configured Vapi assistant and a real test call would be a separate validation step.

Appendix – Screenshots
